Vinylacetylene derivatives. II. N. Kozlov and E. Gimpelovich. *Sinot. Koucha* 4, No. 4, 31-4 (1936); cf. Zelinskii, Kozlov, Shter and Fedin, *C. A.* 27, 6010. Chloroprene was prepd. from 35 g. of HCl (d. 1.19), 5 g. of Cu_2Cl_2 , and 2 g. of NH_4Cl , in 10 g. com. vinylacetylene with the addn. of 100 g. of C_6H_5Mcs . The fraction b. 50

72° contained chloroprene, the yield of which, calcd. from the vinylacetylene, was 83%. The lighter part of the fraction polymerised after 4, and the heavier after 7, days. NH_4OH promotes polymerisation and improves the plasticity. Aq. emulsions in the presence of NH_4OH yielded a material which was suitable for impregnation. A synthetic rubber prepd. from a mixt. of chloroprene and isoprene is unstable, and becomes sticky in air. The best emulsions were obtained from chloroprene which was left standing before being mixed with water. Fourteen references.

Catalytic condensation of acetylene with aromatic amines. IV. Condensation of acetylene with aniline and *p*-toluidine in the presence of silver nitrate. N. S. Koslov and R. Pashenkova. *Izv. Akad. Nauk SSSR Khim. 1961* 11(12):11, 4-50, 4964; *ibid.* 1962 11(12):11, 4-50, 4964. Condensation of acetylene with aniline and *p*-toluidine in the presence of AgNO₃ gave mixtures of stereoisomers of diethyldeneaniline bases (cf. Elimer, *Ann.* 318, 64; Miller, Plochl and Eckstein, *Ber.* 28, 2630, 2672). These bases on distn. gave quinaldine and *p*-methylquinaldine, resp., and some tetrahydroquinolines. V. Condensation of acetylene with *o*- and *p*-anisidine in the presence of CuCl₂ and HgCl₂. N. S. Koslov and R. Pashenkova. *Ibid.* 1961 11(12):11, 4-50, 4964. Treating *o*- and *p*-anisidine in toluene in the presence of CuCl₂ and HgCl₂ with excess C₂H₂ formed the corresponding diethyldeneanilines. These bases on distn. gave *o*- (I) and *p*-methoxyquinaldine (II). Conducting the reaction in alc. and allowing the reaction product to crystallize resulted in diethyldene-*o*-anisidine, m. 102.5° (Me₂CO), this on distn. gave I, m. 123.5° *p*-Anisidine gave 2 stereoisomeric diethyldene-*p*-anisidines, m. 104° and 106°. These on heating gave II, b.

170.0°. VI. Condensation of acetylene with aniline in the presence of mercurous chloride, mercuric chloride and mercuric bromide. N. S. Koslov, R. Pashenkova and T. Rubina. *Ibid.* 1961 11(12):11, 4-50, 4964. The condensation of acetylene with aniline in the presence of mercuric iodide N. S. Koslov and R. Pashenkova. *Ibid.* 1962 11(12):11, 4-50, 4964. The results are the same as above. Chas. Blatt

TITLE: Immune diffusion studies of smooth muscle extracts [This paper was presented at the 29th Meeting of the Hungarian Physiological Society held in Szeged from 2 to 4 July 1964]

SOURCE: Academia scientiarum hungaricae. Acta physiologica, v. 26, Supplement, 1965, 25

TOPIC TAGS: antigen, immunology, protein, myology, rabbit, serum

ABSTRACT: Investigations have been carried out in order to determine whether smooth muscles contain specific protein components different from those in other tissues, mainly in striated muscles. Homogenates of different smooth muscles of the dog were extracted with a 0.154 M KCl solution. The supernatant fluid obtained after centrifugation was examined as a myogen solution, the sediment, extracted with Weber's

Card 1/2

L 14893-66

ACC NR: AT6007403

solution, was examined as a structure protein solution. Extracts were also prepared from striated muscles and parenchymal organs by a similar procedure. Rabbits were immunized with the extracts and the antigens were combined with pure or absorbed immune sera. It was shown that the "anti-smooth muscle myogen" immune serum contains two components while the immune serum against smooth muscle structural protein contains one specific antigenic component. The potential role of these antigenic components in smooth muscle activity has been discussed. [JPRS]

TITLE: On a class of equations solved with respect to a function

PERIODICAL: Referativnyy zhurnal, Matematika, no. 9, 1962, 25, abstract 9B132
("Zesz. nauk. Politechn. czestochow.", 1960, no. 7, 3 - 6; Polish;
Summaries in Russian, English)

TEXT: The paper considers an equation of the form

$$y' = xy + \varphi(x) f(y') + g(y'). \quad (1)$$

By differentiating both sides, it is brought into the form

$$-f(z) u' = g'(z) + f'(z) u + \varphi^{-1}(u), \quad (2)$$

where $z = y'$, $u = \varphi(x)$, φ^{-1} is the function inverse to φ . The functions $\varphi(x)$ for which equation (2) takes the form of known equations are indicated and consequently equation (1) is solved by known methods.

TITLE: Dependence of the Mechanical Properties of Electrically-
deposited Copper on the Regime of Electrolysis and the
Composition of the Electrolyte (Zavisimost' mekhanicheskikh
svoystv elektroosazhdennoy medi ot rezhima elektroliza i
sostava elektrolita)

PERIODICAL: Metallovedeniye i Obrabotka Metallov, 1958, No. 2,
pp. 35 - 37 (USSR).

ABSTRACT: Literary data on the mechanical properties of copper
obtained in sulphuric acid electrolytes are inadequate and
contradictory. This is attributed to the fact that individual
authors tested electrolytically deposited layers which were
produced under differing electrolysis regimes in electrolytes
of various compositions and differing subsequent heat treat-
ments. ~~For~~ determining the mechanical properties of electrically
deposited copper and elucidating the dependence of these
properties on the cathode current density in the electrolyte
the authors of this paper carried out special

129-2-7/11

Dependence of the Mechanical Properties of Electrically Deposited Copper on the Regime of Electrolysis and the Composition of the Electrolyte.

a wall thickness of 1 mm was used. The deposition of copper on the patterns was effected simultaneously in two electrolytes, one consisting of 250 g/litre of blue vitriol, 70 g/litre of sulphuric acid and an addition of 10 g/litre of ethyl alcohol, and the other one consisting of the same electrolyte but without the addition. The electrolysis in the electrolyte with ethyl alcohol was effected with a current density of 1.8, 5, 10, 15, 20 and 25 A/dm², whilst the current density for the electrolyte not containing ethyl alcohol addition was 1.8 and 5 A/dm², respectively. Under each regime, 10 specimens were produced. The specimens produced in the electrolyte without the ethyl alcohol addition, using a current density of 1.8 A/dm², had a strength of 12 kg/mm², a relative elongation of 11% and, in the case of a current density of 5 A/dm², the respective values were 17 kg/mm² and 16.2%. The dependence of the strength and the relative elongation of electrolytic copper on the current density in electrolytes with ethyl alcohol addition are graphed in Fig. 1. The Debye patterns, obtained by V.M. Rozenberg (Fig. 2), show that from a current density

Dependence of the Mechanical Properties of Electrically Deposited
Copper on the Regime of Electrolysis and the Composition of the
Electrolyte. 129-2-7/11

of 15 A/dm^2 onwards, a texture is observed if a surface-active substance is present. It is concluded that the strength and the relative elongation of the electrolytic copper can be varied by varying the current density during electrolysis and introducing a surface-active substance into the electrolyte. The strength of copper deposited with a current density of

25 A/dm^2 inside electrolytes containing ethyl alcohol addition approaches the maximum attainable strength of copper components after various types of mechanical working and the relative elongation drops to 2%. The increase in the strength of electrolytically deposited copper with increasing current density and presence of a surface-active substance is attributed to the texturing of the deposit. There are 2 figures and 2 Slavic references.

TITLE: The Dissolution of Aluminum in Acids and Lyes in the Ultrasound Field (Rastvoreniye alyuminiya v kislotakh i shchelochakh v ul'trazvukovom pole)

PERIODICAL: Zhurnal prikladnoy khimii, 1959, Vol XXXII, Nr 3. pp 563-566 (USSR)

ABSTRACT: Aluminum dyes are used in galvanoplastic processes for the production of hollow parts. After electric precipitation the dyes are dissolved in NaOH or HCl solution. The application of ultrasound accelerates the dissolution. For NaOH the best results were obtained at 60°C and a frequency of 16 kilocycles with an intensity of w/cm^2 . In HCl solution with ultrasound applied the dissolving rate is at first decreased, but at a frequency of 16 kilocycles and an intensity of $1.3 w/cm^2$ the process is accelerated. On the anode aluminum forms a hydroxide which dissolves by forming aluminate. This diffuses in the solution. In HCl solution easily soluble aluminum chloride is formed.

AUTHORS: Gracheva, M. P., and Gliner, A. M., Candidate of Technical Sciences

TITLE: Protective and ornamental films on aluminum

PERIODICAL: Mashinostroitel', no. 5, 1961, 42

TEXT: The author describes the production method of "ematal"-films, i. e. opaque oxidation films on aluminum. These films are generally produced in electrolytes containing titanium salts. The technological process of "ematalirovaniye" consists of the following: polishing - which should be carried out with pastes of high quality. The authors recommend white pastes on the base of aluminum oxide and French chalk; degreasing in organic solvents, e. g. gasoline, kerosene or white spirit; mounting on supports - the material for the supports should be pure aluminum or AMГ (AMG) and AMЦ (AMTs) alloys; chemical degreasing, which should be effected in a solution containing 10 g/liter caustic soda, 50 g/liter sodium triphosphate and 5 g/liter water glass. The solution temperature should be 60-70°C, the holding time 2-3 minutes. Preliminarily polished parts should be chemically degreased in a solution consisting of 10-15 g/liter mono- or di-derivatives of sodium phosphate and 5-10 g/liter ОП-7 (OP-7). The solution

Card 1/2

21902

Protective and ornamental films on aluminum

S/117/61/000/005/005/009
A004/A104

temperature should be 80-100°C, holding time 5-15 minutes, pH = 5.5-8.5; purification - to eliminate the grayish film from the surface forming during degreasing. This operation is carried out in a 30% nitric acid solution at 18-20°C; "ematalirovaniye", which is effected in an electrolyte containing 30 g/liter chromium anhydride and 1-2 g/liter boric acid. The process should take place at 45-50°C, holding time is one hour. At first the voltage is brought to 40 v and held for 30 minutes, during which the current density should amount to 0.4-0.5 amp/dm². Then the voltage is raised to 80 v for another 30 minutes while the current density is brought to 1.0 amp/dm². The processing conditions for the AMG and AMTs alloys are analogous; treatment in nitric acid solution - this operation is necessary to obtain rich colors during the painting of the film. 25-30% nitric acid is used at temperatures of 18-20°C, holding time is 1-2 minutes. Painting of the parts is carried out in aqueous solutions of organic dyes immediately after "ematalirovaniye". The pH-value of the dyestuffs greatly affects the quality of the paint. The pH-value can be corrected with the aid of acetic acid; sealing - during this operation the film pores are sealed and the dyestuff in the pores is fixed. Sealing is effected in distilled water, after which the parts are dried at 100°C. There is 1 table.

Ginberg, Aleksandr Mironovich.

Tekhnologiy. gal'vnotekhnika (Technology of Electroplating) Lenin-
grad, Sudpromgiz, 1962. 279 p. 13,300 copies printed.

Reviewer: G. T. Bakhvalov, Doctor of Technical Sciences; Scientific
Ed.: I. D. Gruyev; Ed.: N. N. Vasil'yeva; Tech. Ed.: R. K. Tsai.

PURPOSE: This book is intended for foremen and workmen of electro-
plating plants.

COVERAGE: The book reviews modern electroplating processes, as well
as anodizing and chemical coating processes and those electroform-
ing processes which are widely employed in the instrument-making
and machine-building industries. Zinc, cadmium, copper, silver,
nickel, and chromium electroplating procedures are discussed at
length. In view of the wide use of aluminum, magnesium, and ti-
tanium as structural materials, the problems of coating these
metals and their alloys are dealt with in detail. No personalities
are mentioned. There are 73 references, all Soviet.

TITLE: Influence of the structure of the copper substrate
on the structure of electrodeposited nickel

PERIODICAL: Zhurnal prikladnoy khimii, v. 35, no. 12, 1962,
2679-2683

TEXT: The effect of varying certain conditions of electro-
deposition on the influence exerted by the orientation of a coarse-
grained copper substrate on the structure of an electrodeposited
nickel film was investigated. It was found that in the electrodepo-
sition of nickel from the usual sulfate-type solutions on to very
coarse-grained copper, the latter always exerts a pronounced influ-
ence on the orientation of the deposit. The film thickness to which
this influence persists depends however on the conditions of electro-
deposition. One of the governing factors is current density. With
increase in current density, the influence of the basis metal orien-
tation ceases at ever-decreasing film thicknesses, and a change in

Card 1/2

Influence of the structure ...

S/080/62/035/012/007/012
D217/D307

current density after the film has attained a thickness of above 2000 Å has a particularly pronounced effect from this point of view. The grain size and orientation at the substrate surface has a marked bearing on the film thickness to which the orientation effect persists. The latter increases with increase in grain size. In the electrodeposition of nickel on to coarse-grained copper, nickel grains of various sizes and orientations can form on the same specimen owing to the edge effect. There are 6 figures.

TITLE: The structure of nickel plates precipitated in an ultrasonic field and the possibility of obtaining bright sediment

SOURCE: Vses. sovesh. po teor. i prak. bles. gal'. Vilnius, 1962. Teor. i prak. bles. gal' (Theory and practice of bright electroplating), osnovnyye materialy*, 1963, 75-82

TOPIC TAGS: sediment, ultrasonic field, plating, nickel plate, nickel plating, nickel plate structure

ABSTRACT: There are different points of view in the literature on the growth of crystals in electrolytes under the simultaneous influence of ultrasonic waves. A. Roll (Z. Metallkunde, 41, Nr 11, 238 (1950)) writes that silver grains become coarse. Fr. A. Levi (Ricerca scient., 19, 867 (1949)) showed that silver precipitated in an ultrasonic field becomes finer. The present authors explain this phenomenon by the difference in electrolyte content, current and temperature, and the intensity of the ultrasonic waves. Their investigation showed that electrolysis of nickel in an ultrasonic field with currents allowable for the given

1/3

ACCESSION NR: AT4017655

electrolyte leads to an enlargement of the structure. The use of an ultrasonic field when the current density is above the maximum allowable value leads to the formation of fine crystals. It is assumed that the effect of the ultrasonic field during nickel plating is connected with action of the sound on the secondary processes at the cathode, namely the formation and dispersion of nickel hydroxide (see Fig. 1 of the Enclosure). ABSTRACT: The mechanism of formation and structure of opaque oxide films was studied on samples of aluminum AV000, A00, AD1 and aluminum alloys D1, D16,

Cord 1/3

ACCESSION NR: AT4043074

AMts and AMg (compositions given). Samples were prepared by chemical degreasing and bleaching (30% HNO₃), then anodized in various baths under different conditions of temperature, voltage, duration and pH. Structural analyses of the films obtained utilized the carbon-colloid replica method and a magnification of 22000:1 on an electron microscope EM-3. It was established that opacity is not governed by sample composition, nor can it result from penetration of metal hydroxides into the film pores or the filling of films, but probably depends on film structure and the corresponding quantity and dimensions of the pores. Stepwise modification of the current density facilitates formation of an opaque film. The presence of pores and a cellular structure was confirmed. The latter is rearranged as the current density increases by stages; the oxide cell dimensions increase in the cell formation area and the number of cells per unit of surface decreases correspondingly. Pore diameters in the surface layers of films vary little during oxidation. A sharp discrepancy develops between the number of cells on the metal surface and the number of pores on the external surface of films. The number of pores becomes greater than the number of cells when the current density is increased by stages.

TITLE: Effect of the ultrasonic field on parkerizing and properties of phosphate coatings

SOURCE: Zhurnal prikladnoy khimii, v. 37, no. 3, 1964, 553-557

TOPIC TAGS: Ultrasound, parkerizing, phosphate coating, corrosion property, porosity, electrical stability, ultrasonic field

ABSTRACT: The possibility of intensifying the parkerizing process of ferrous metals and improving the physico-mechanical and corrosion properties of phosphate films with the aid of ultrasonics was studied. The possibility of substituting the sandblast treatment of the surface of products, which was usually employed before parkerizing and provided the best results, is studied with ultrasound parkerizing. The superimposition of the ultrasonic field during parkerization makes it possible to precipitate qualitative phosphate films in steel without sandblast treatment. The phosphate films obtained in the ultrasound field with 16-22 kc frequency for 40-60 minutes are less porous and differ by more highly

Card 1/2

ACCESSION NR: AP1024766

anti-corrosive properties, electrical stability, and finer structure. Parkerization in the ultrasonic field makes it possible to obtain a coating with the same (and in many cases superior) properties as coatings obtained in steel with preliminary sandblasting. Orig. art. has: 2 tables, 3 figures

TITLE: Effect of ultrasound on the electrodeposition of Ni-Fe-Mo alloys

SOURCE: Elektrokhiymiya, v. 2, no. 5, 1966, 551-556 18 27 21 27

TOPIC TAGS: electrodeposition, alloy electrodeposition, nickel alloy, iron containing alloy, molybdenum containing alloy, ultrasound effect

ABSTRACT: The effect of ultrasound on the electrodeposition of Ni-Fe-Mo alloys from a sulfate electrolyte containing 2.2—18.0 g/l sodium molybdate has been investigated. The alloys deposited without ultrasound contained less than 1% molybdenum, regardless of molybdate concentration. At concentrations of molybdate higher than 12 g/l, the deposits were dark and cracked owing to high internal stresses. Ultrasound with an intensity of 0.9—1.04 W/cm² and a frequency of 22—26 kc had a beneficial effect on the electrodeposition: process and quality of alloys. At a molybdate concentration of 8—10 g/l, the Mo content in the alloy was 4—5%, the internal stresses in deposit decreased, and the deposits were dense and lustrous. The optimum pH of the electrolyte was found to be 2.3—2.7 and the optimum current density, 40—60 a/dm².

TEXT: The determination of Nb in carbonatites having a predominant content of calcite, as well as a high P-content, requires decomposition of the sample in acetic acid. The insoluble, Nb-containing residue is dissolved and the spectrophotometric determination performed by using NH_4SCN as agent. 0.4 g of the rock is heated for 1 hr with 20 ml of 25 % acetic acid on a water bath with stirring. The insoluble residue is filtered off, and washed out with 0.5% acetic acid. Filter + residue are incinerated in a quartz crucible, and the ashes are fused with 1.25-2.5 g $\text{Na}_2\text{S}_2\text{O}_7$ or $\text{K}_2\text{S}_2\text{O}_7$. The melt is dissolved in 12.5-25 ml tartaric acid (15 %), the

TITLE: Effect of ultrasound on the electrodeposition of Ni-Fe-Mo alloys

SOURCE: Elektrokimiya, v. 2, no. 5, 1966, 551-556 18 27 27 27

TOPIC TAGS: electrodeposition, alloy electrodeposition, nickel alloy, iron containing alloy, molybdenum containing alloy, ultrasound effect

ABSTRACT: The effect of ultrasound on the electrodeposition of Ni-Fe-Mo alloys from a sulfate electrolyte containing 2.2—18.0 g/l sodium molybdate has been investigated. The alloys deposited without ultrasound contained less than 1% molybdenum, regardless of molybdate concentration. At concentrations of molybdate higher than 12 g/l, the deposits were dark and cracked owing to high internal stresses. Ultrasound with an intensity of 0.9—1.04 W/cm² and a frequency of 22—26 kc had a beneficial effect on the electrodeposition process and quality of alloys. At a molybdate concentration of 8—10 g/l, the Mo content in the alloy was 4—5%, the internal stresses in deposit decreased, and the deposits were dense and lustrous. The optimum pH of the electrolyte was found to be 2.3—2.7 and the optimum current density, 40—60 A/dm².
